TASK 5 — HISTORICAL EVENTS AND INTERPRETATION OF THE SAIKU ANALYSES

A. Long-run growth: GDP per capita since 1900

The first export displays annual GDP per capita for Portugal and comparison countries from 1900 to 2022, with years nested under decade headings. Portugal rises from 2,075 in 1900 to 28,992.1 in 2022, measured in 2011 international dollars. The annual series reveals turning points that are less visible in decade summaries.

Portugal's acceleration from 4,712 in 1960 to 11,258 in 1973 coincides with events describing EFTA membership in 1960, economic opening and industrial transformation. Spain also records substantial growth over this period, consistent with the supplied event describing its 1960–1973 economic expansion. These entries contextualize the parallel trajectories without establishing how much growth each development generated.

The Portuguese series falls from 11,258 in 1973 to 10,388 in 1975. The events dataset records the 1973 oil crisis, the 1974 revolution and the nationalizations, decolonization and population movements of 1975. Their proximity to the downturn makes them relevant annotations, but the series cannot separate their individual effects. Portugal exceeds its 1973 level by 1977; the supplied event narratives should therefore not be used to claim a much later recovery of that level.

EEC accession in 1986 provides context for subsequent expansion: Portugal's GDP per capita increases from 13,774 in 1986 to 23,372 in 2000. Euro adoption in 1999 and the introduction of notes and coins in 2002 are further institutional milestones, but neither implies uninterrupted convergence. Growth becomes slower and uneven during the 2000s. The decline from 25,590.9 in 2008 to 24,902.5 in 2009 coincides with the global financial crisis. The fall from 25,463.2 in 2010 to 24,120 in 2013 overlaps the sovereign-debt crisis and the 2011 financial-assistance programme. The 2020 pandemic provides context for the fall from 28,056.1 in 2019 to 25,700.3 in 2020, followed by recovery in 2021–2022.

Comparison-country annotations include Spain's 1936–1939 Civil War and Germany's wartime disruption and postwar recovery. Such events help explain why a smooth long-run trend can conceal severe interruptions. Historical coverage differs by country, and the 2020s contain only 2020–2022. Decade headings in this export organize annual observations; they are not themselves displayed decade-average results.

B. European comparison

The second export compares annual total GDP for Portugal and seven Western European countries from 1975 to 2022. Total GDP measures economic size, not income per person. Portugal's GDP rises from approximately 136.5 billion in 1986 to 238.8 billion in 2000, in the Maddison GDP units used by the warehouse. The 1986 EEC accession events for Portugal and Spain contextualize this expansion. Their timing alone does not prove accession caused the observed growth.

The financial crisis and sovereign-debt events contextualize the interruption after 2008. Portugal's GDP falls from approximately 267.3 billion in 2010 to 250.4 billion in 2013. Greece's GDP falls from approximately 316.0 billion in 2008 to 241.7 billion in 2013, alongside the event describing its 2010 debt crisis and bailout. Spain's housing and banking-crisis entries provide context for its weaker performance during this period. The

pandemic entry also corresponds to Portugal's GDP decline from approximately 286.5 billion in 2019 to 262.7 billion in 2020.

The supplied export does not contain GNI per capita, life expectancy or the required Eastern European comparison from 1990 onward. No results for those components are claimed here. They require additional Society-cube and Eastern European analyses. Transition and European-integration events should then be annotated against those countries' actual observations rather than inferred from the Western European GDP table.

C. Structural transformation and sector drill-down

The third export shows the Broad Sector → Sector hierarchy and average value-added shares. Portugal records Agriculture 2.465%, Industry 21.048%, Manufacturing 12.971% and Services 63.697%. The EU benchmark records 1.832%, 23.946%, 15.943% and 63.743%, respectively. Portugal's displayed services share is therefore close to the EU figure, while its industry and manufacturing shares are lower.

Portugal's 1960 industrial-transformation and 1986 European-integration events provide background for discussing economic restructuring. However, this export has no displayed year dimension and its summary sheet does not specify a time filter. It cannot establish when sector shares changed or link a particular change to an event. A dated comparison or time series is required before claiming a shift towards services from this export.

Manufacturing is included within industry and must not be added to it. The XML uses AVG for value_added_pct_gdp, so averages depend on available observations and are not weighted regional shares. Broad-sector aggregates must also be interpreted according to that rule, rather than as automatically additive totals.

Overall interpretation

The exports support a narrative of substantial long-run Portuguese development interrupted by major shocks, together with a service-oriented sector composition. Historical events make these results more interpretable, but do not replace missing analyses or demonstrate causality. Time coverage, units, aggregation rules and overlapping sector definitions remain essential qualifications.
